

Poster-board at AAO Annual Session 2005 in San Francisco, CA

We have officially started the effort of defining an informatics standard for orthodontics, and have deadlines! We decided to divulge the news through a scientific posterboard at the biggest orthodontic convention in the world. Software vendors, doctors or anyone interested should know about this project.

We have officially started the effort of defining an informatics standard for orthodontics, and have deadlines! We decided to divulge the news through a scientific posterboard at the biggest orthodontic convention in the world. Software vendors, doctors or anyone interested should know about this project.

Our posterboard got accept before we started to collaborate with the [American Dental Association](#) (ADA) Standards Committee for Dental Informatics (SCDI). What this means is that the course of the project changed quite a bit from when we wrote the initial abstract for the poster until when it was up on display. The title of the project, for instance, probably would have never been *PANIO* had I been introduced to the ADA SCDI earlier. But we figured *PANIO* actually sounded pleasing to the ear in all languages, and that we should therefore take advantage of this opportunity and keep the name.

The [scientific poster](#) occupies the full 8'x4 provided tackboard. It provides the viewer with a broad perspective of what a software standard is and why it is needed in the field of orthodontics. At its center there is a description of the ADA SCDI and [DICOM](#) structures. This part was influenced by the newly established collaboration with them.

In addition, [PANIO: The First Orthodontic Standard \(handout\)](#) was provided for the more interested. All four sides of the handout were printed on a single Letter size booklet, and provided the reader with a little extra information such as references, more names on collaborators and more detail on the individual working groups.

Abstract

[Software standards](#) are becoming increasingly popular in the medical field, reducing the risk of patient data loss and allowing for greater patient data interchange. Many medical fields have either already developed or are currently developing standards like DICOM and ADA SCDI. Yet there still exists no software standard in the orthodontic field. Our goal is to develop a public orthodontics software standard, approved by clinicians, developers and accredited institutions worldwide. In collaboration with: ADA and DICOM.

Plan: 1) extend DICOM to accommodate all orthodontics data needs. 2) Include the instructions of the extended DICOM standard in an ADA Technical Report; 3) prove the functionality of the standard by writing a program that directly implements it. The final products (all standard definitions and the implemented software) are meant to be publicly available free of charge to facilitate their distribution. We hope our presentation will stimulate interest among individuals and institutions to join us in this project.
